**SYNTHESIS OF HUMAN PROCOLLAGENS AND COLLAGENS
IN RECOMBINANT DNA SYSTEMS**

GOVERNMENT RIGHTS

This invention was made in the course of research
5 supported in part by NIH grants AR38188 and AR39740. The
Government may have certain rights in this invention.

BACKGROUND OF THE INVENTION

Expression of many exogenous genes is readily obtained
in a variety of recombinant host-vector systems, but becomes
10 difficult to obtain if the protein normally requires extensive
post-translational processing. This is the likely reason that
expression in a fully recombinant system has not been reported
for any of the major fibrillar collagens that require
processing by post-translational enzymes. See Prockop and
15 Kivirikko, *N. Engl. J. Med.* 1984, 311, 376-386. Prolyl 4-
hydroxylase is probably one of the most important post-
translational enzyme necessary for synthesis of procollagen or
collagen by cells because it is required to hydroxylate prolyl
residues in the Y-position of the repeating -Gly-X-Y- sequences
20 to 4-hydroxyproline. Prockop and Kivirikko, *N. Engl. J. Med.*
1984, 311, 376-386. Unless an appropriate number of Y-position
prolyl residues are hydroxylated to 4-hydroxyproline by prolyl
4-hydroxylase, the newly synthesize chains cannot fold into a
triple-helical conformation at 37°C. If the hydroxylation does
25 not occur, the polypeptides remain non-helical, are poorly
secreted by cells, and cannot self-assemble into collagen
fibrils. Recently, prolyl 4-hydroxylase, was expressed in

- 2 -

baculovirus. Vuorio, K. et al., *Proceedings of the National Academy of Science, U.S.A.*, 1992, 89, 7467-7470.

Schnieke et al., *Proc. Natl. Acad. Sci. U.S.A.* 1987, 84, 8869-8873 and Lee et al., *J. Biol. Chem.* 1989, 264, 20683-5 20687, disclose rescue experiments in two different systems that synthesized only one of the two chains for type I procollagen. Schnieke et al. reported that a gene for the human fibrillar collagen pro α 1(I) chain, the COL1A1 gene, can be expressed in mouse fibroblasts and that the chains are used 10 to assemble molecules of type I procollagen, the precursor of type I collagen. However, in this system the pro α 2(I) chains found in the same molecule are of mouse origin. In the system of Lee et al. the pro α 1(I) chains are of rat origin. Thus, synthesis of a procollagen molecule in which all three chains 15 are derived from an exogenous gene was not obtained by either Schnieke et al. or Lee et al.

Failure to obtain expression of genes for fibrillar collagens in a fully recombinant system has hampered attempts to study the normal structure-function relationships of the 20 proteins and to study the effects of mutations. In particular, mutations in the gene for type II procollagen have recently been implicated as the cause of several human diseases, Anderson et al., *Am. J. Hum. Genet.* 1990, 46, 896-901; Tiller et al., *Proc. Natl. Acad. Sci. U.S.A.* 1990, 87, 3889-3893; 25 Vissing et al., *J. Biol. Chem.* 1990, 264, 18265-18267; Lee et al., *Science* 1989, 244, 978-980; Francomano et al., *Genomics* 1987, 1, 293-296; Knowlton et al., *Am. J. Hum. Genet.* 1989, 45, 681-688; Ahmad et al., *Am. J. Hum. Genet.* 1990, 47, A206; Palotie et al., *The Lancet* 1989, I, 924-927; Knowlton et al., 30 *N. Engl. J. Med.* 1990, 322, 526-530; Ala-Kokko et al., *Proc. Natl. Acad. Sci. U.S.A.* 1990, 87, 6565-6568, but because adequate numbers of human cartilage cells are difficult to obtain and because human chondrocytes readily lose their phenotype in culture, Elima and Vuorio, *FEBS Lett.* 1989, 258, 35 195-198; Aulhouse et al., *In Vitro Dev. Biol.* 1989, 25, 659-668, the causal relationship between a mutation in the gene and

- 3 -

the biological function of the protein has proven elusive.

Also, failure to obtain expression of genes for human fibrillar collagens has made it impossible to prepare human fibrillar procollagens and collagens that have a number of 5 therapeutic uses in man and that will not produce the undesirable immune responses that have been encountered with use of collagen from animal sources.

Recently however, Applicants described the expression of a human type II procollagen in mouse 3T3 cells using a 10 promoter from the human type I procollagen gene. Ala-Kokko et al., *J. Biol. Chem.* 1991, 266, 14175; Ala-Kokko et al., *Matrix* 1990, 10, 234.

SUMMARY OF THE INVENTION

The present invention involves the preparation of gene 15 constructs that contain collagen genes of human and other origins. One of the gene constructs is hybrid of a human gene for type I procollagen (COL1A1) and a human gene for type II procollagen (COL2A1). The 5'-end of the construct contains the promoter, exon 1 and intron 1 of the COL1A1 gene fused to 20 intron 1 of the COL2A1 gene. The construct is designed so that the promoter and putative enhancer in the first intron of the COL1A1 drive expression of the COL2A1 gene and cause production of human type II procollagen. The COL2A1 gene consisted of two SphI/SphI fragments of the gene totalling about 26,000 base 25 pairs. This construct contains all the coding sequences of the gene except for the few codons of a signal peptide in exon 1 and an alternatively spliced exon that follows exon 1. Some versions of the construct also include a 3,500 base pair SphI/SphI fragment from the 3'-end of the gene that is needed 30 for correct polyadenylation of the mRNA.

A second construct has the promoter, the first exon, the intron, and about half of the second exon of the human COL1A1 gene as the 5'-fragment of the construct. The 5'-fragment is joined through a unique KpnI restriction 35 endonuclease site to a cDNA that contains all the coding sequences of the gene except for those contained in the first

- 4 -

one and one-half exons. In addition, the 3'-end of the cDNA is linked through an EcoRI site to an EcoRI/EcoRI fragment of about 0.5 kb from the 3'-end of the COL1A1 gene. A series of additional constructs use the highly active promoter for the 5 cytomegalic virus to drive expression of full-length cDNA, for the human COL1A1 gene. All the constructs have been engineered so that they have unique restriction endonuclease sites at their 5'- and 3'-ends and, therefore, can be excised from vector sequences.

10 The present invention involves transfection and expression of collagen gene constructs into selected cells. In some preferred embodiments of the present invention, selected cells express one or more post-translational enzymes important to the biosynthesis of procollagens and collagens. For 15 example, prolyl 4-hydroxylase is a post-translational enzyme important to the biosynthesis of procollagens and collagens. The enzyme must hydroxylate about 100 prolyl residues in the Y position of the repeating -Gly-X-Y tripeptide structures of procollagens and collagens to 4-hydroxyproline in order for the 20 procollagens or collagens to fold into a stable triple-helical conformation at body temperature of the organism synthesizing the protein. Thus, in some preferred embodiments of the present invention cells which express prolyl 4-hydroxylase are preferred. Such cells may naturally express the post- 25 translational enzymes, or may be transformed with genes coding for post-translational enzymes such as prolyl 4-hydroxylase. Mammalian cells, insect cells, or yeast cells are preferred. Mammalian cells, insect cells and yeast cells which are transfected with at least one set of genes coding for a post- 30 translational enzyme such as prolyl 4-hydroxylase, may also be transfected with collagen gene constructs in yet other preferred embodiments of the present invention. The invention can also employ other cells that can be cultured and contain the necessary post translational enzymes and secretory 35 mechanisms, such as chinese hamster ovary cells.

- 5 -

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a photograph showing analysis by polyacrylamide gel electrophoresis in SDS of the proteins secreted into medium by HT-1080 cells that were transfected 5 with a gene construct containing the promoter, first exon and most of the first intron of the human COL1A1 gene linked to 30 kb fragment containing all of COL2A1 except the first two 10 exons. The cells were incubated with [¹⁴C]proline so that the medium proteins could be analyzed by autoradiography (storage 15 phosphor film analyzer). Lane 1 shows that the unpurified medium proteins are comprised of three major polypeptide chains. The upper two are pro α 1(IV) and pro α 2(IV) chains of type IV collagen that are synthesized by cells not transfected by the construct (not shown). The third band is the pro α 1(II) 20 chains of human type II procollagen synthesized from the construct. Lanes 2 and 3 are the same medium protein after chromatography of the medium on an ion exchange column (DE-52, Whatman, at pH 7.4 in lane 2 and at pH 7.0 in lane 3). The type II procollagen appeared in the void volume of the ion 25 exchange column.

Figure 2 is a photograph showing that the type II procollagen secreted into the medium from cells described in Figure 1 was folded into a correct native conformation. The medium proteins were digested at the temperatures indicated 25 with a high concentration of trypsin and chymotrypsin under conditions in which correctly folded triple-helical procollagen or collagen resists digestion but unfolded or incorrectly folded procollagen of collagen is digested to small fragments (Bruckner and Prockop, *Anal. Biochemistry* 1981, 110, 360). The 30 products of the digestion were then analyzed by polyacrylamide gel electrophoresis in SDS and fluorography. The results show that the type II procollagen resisted digestion up to 43°C, the normal temperature at which type II procollagen unfolds. Therefore, the type II procollagen is correctly folded and can 35 be used to generate collagen fibrils.

Figure 3 is a photograph showing analysis of medium of HT-1080 cells co-transfected with a gene for COL1A1 and a

- 6 -

gene for COL1A2. THE COL1A2 was linked to an active neomycin-resistance gene but the COL1A1 was not. The cells were screened for expression of the COL1A2-neomycin resistance gene construct with the neomycin analog G418. The medium was 5 analyzed for expression of the COL1A1 by Western blotting with a polyclonal antibody specific for the human pro α 1(I) chain. Lane 1 indicates that the medium proteins contained pro α (I) chains. Lane 2 is an authentic standard of type I procollagen containing pro α 1(I) chains and partially processed pC α 1(I) 10 chains. The results demonstrate that the cells synthesized human type procollagen that contained pro α 1(I) chains, presumably in the form of the normal heterotrimer with the composition two pro α (I) chains and one pro α 2(I) chain.

Figure 4 is a schematic representation of the cDNA for 15 the pro α 1(I) chain of human type I procollagen that has been modified to contain artificial sites for cleavage by specific restriction endonucleases.

Figure 5 is a photograph showing analysis by non-denaturing 7.5% polyacrylamide gel electrophoresis (lanes 1-3) 20 and 10% polyacrylamide gel electrophoresis in SDS (lanes 4-6) of purified chick prolyl 4-hydroxylase (lanes 1 and 4) and the proteins secreted into medium by Sf9 cells expressing the gene for the α -subunit and the β -subunit of human prolyl 4-hydroxylase and infected with α 58/ β virus (lanes 2 and 5) or 25 with α 59/ β virus (lanes 3 and 6). α 58/ β and α 59/ β differ by a stretch of 64 base pairs. Lanes 1-3 are protein separated under non-denaturing conditions and showing tetramers of the two kinds of subunits. Lanes 4-6 are the same samples separated under denaturing conditions so that the two subunits 30 appear as separate bands.

DETAILED DESCRIPTION OF THE INVENTION

It has been established that most forms of osteogenesis imperfecta (OI) are caused by dominant mutations in one of the two genes for type I procollagen. Also, at least 35 a subset of post-menopausal osteoporosis is caused by similar mutations in the two genes for type I procollagen. It has

- 7 -

further been reported that mutations in the type II procollagen gene cause human diseases such as chondrodysplasia, and a subset of primary generalized osteoarthritis. It has further been reported that mutations in the type III procollagen gene 5 (COL3A1) cause human diseases such as a lethal variant of Ehlers-Danlos syndrome (type IV) and familial aneurysms. Moreover, it has been demonstrated that the kidney disease known as the Alport syndrome is caused by mutations in one of the genes (COL4A5) for type IV collagen. It has further been 10 demonstrated that injections of suspensions of collagen fibers are effective for the treatment of cosmetic defects as well as physical weakness of tissues such as sphincters.

The present invention concerns cells in which one of these fibrillar procollagens is expressed both as mRNA and 15 as a protein. Additionally, the present invention concerns types I, II, and III procollagens expressed in a mammalian cell line, an insect cell line, or a yeast cell line, and the establishment of transfected cell lines comprising these procollagen genes.

20 The present invention further provides that the gene constructs can be used to synthesize human fibrillar procollagens in the HT-1080 human tumor cell line. This human cell line has been a ready source of type IV collagen, the major collagen of basement membranes. Because type IV collagen 25 is not a fibril-forming procollagen or collagen, it can be readily separated by a simple chromatographic procedure from any fibrillar procollagen. Hence, the invention provides methods whereby a human fibrillar procollagen can be readily separated from products of an endogenous collagen gene. 30 Moreover, HT-1080 cells grow extremely rapidly in culture and can be maintained for long periods of time.

Additionally, the present invention provides for a single procollagen or collagen gene or a number of different procollagen or collagen genes expressed within a cell. 35 Further, it is contemplated that there can be a one or more copies of a single procollagen or collagen gene or of the number of different such genes transfected into cells and

- 8 -

expressed. The present invention provides that these cells can be transfected so that they express at least one human procollagen gene, especially but not limited to the COL1A1 gene encoding the pro α 1(I) procollagen chain of human type I procollagen. It is also provided that the cells can be transfected with and express both COL1A1 and COL1A2 genes so that both pro α 2(I) and pro α 1(I) chains are simultaneously synthesized and assembled into normal heterotrimeric molecules of type I procollagen. Moreover, the present invention provides that cells can be transfected with and express the COL2A1 gene encoding the pro α 1(II) chain of human type II procollagen. It is further provided that cells can be transfected with and express the COL3A1 gene encoding the pro α 1(III) chain of type III procollagen. The invention also provides that any procollagen or collagen gene transfected into and expressed within cells may comprise a mutant, variant, hybrid or recombinant gene. Such mutant, variant, hybrid or recombinant gene may include a mutation which provides unique restriction sites for cleavage of the hybrid gene. In some preferred embodiments of the present invention, mutations providing one or more unique restriction sites do not alter the amino acid sequence encoded by the gene, but merely provide unique restriction sites useful for manipulation of the gene. Thus, the modified gene would be made up of a number of discrete regions, or D-regions, flanked by unique restriction sites. These discrete regions of the gene are herein referred to as cassettes. For example, cassettes designated as D1 through D4.4 are shown in Figure 4. Multiple copies of a gene cassette is another variant of the present gene which is encompassed by the present invention. Recombinant or mutant genes or cassettes which provide desired characteristics such as resistance to endogenous enzymes such as collagenase are also encompassed by the present invention. Further, the present invention provides transfected cells substantially all of which comprise other procollagen or collagen genes, preferably but not limited to types I, II, III procollagen genes or type IV collagen genes. The present invention contemplates that

- 9 -

transfected cells may be mammalian cells such as human tumor cells, especially but not limited to HT-1080 cells. In other embodiments of the present invention, transfected cells are insect cells such as baculovirus Sf9 cells. In still other 5 embodiments of the present invention, transfected cells are yeast cells, such as *Saccharomyces cerevisiae* or *Pichia pastoris* cells. In preferred embodiments of the present invention, cells such as mammalian, insect and yeast cells, which may not naturally produce sufficient amounts of post 10 translational enzymes, are transformed with at least one set of genes coding for a post-translational enzyme such as prolyl 4-hydroxylase.

The present invention further contemplates cells substantially all of which comprise at least one transfected 15 human procollagen or collagen gene having at least one chain derived from a transfected or collagen procollagen gene or genes and at least one chain derived from an endogenous human or non-human procollagen gene or genes, other than the $[\text{pro}\alpha 1(\text{I})]_2\text{pro}\alpha 2(\text{I})$ collagen molecule consisting of human 20 $\text{pro}\alpha 1(\text{I})$ moieties and non-human $\text{pro}\alpha 2(\text{I})$ moieties, or non-human $\text{pro}\alpha 1(\text{I})$ moieties and human $\text{pro}\alpha 2(\text{I})$ moieties.

A novel feature of the methods of the invention is that relatively large amounts of a human fibrillar procollagen can be synthesized in a recombinant cell culture system that 25 does not make any other fibrillar procollagen. Systems that make other fibrillar procollagens or collagens are impractical because of the extreme difficulty of purifying the product of the endogenous genes for fibrillar procollagen or collagen from products of the recombinant genes. Using methods of the 30 present invention, purification of human procollagen is greatly facilitated. Moreover, it has been demonstrated that the amounts of protein synthesized by the methods of the present invention are high relative to other systems used in the art.

Other novel features of the methods of present 35 invention are that procollagens synthesized are correctly folded proteins so that they exhibit the normal triple-helical conformation characteristic of procollagens and collagens.

- 10 -

Therefore, the procollagens can be used to generate stable collagen fibrils and fibers by cleavage of the procollagens with proteases.

The present invention is in contrast to Schnieke et al., who reported that a gene for the human fibrillar procollagen pro α 1(I) chain, the COL1A1 gene, can be expressed in mouse fibroblasts and the chains used to assemble molecules of type I procollagen, the precursor of type I collagen. However, in the system of Schnieke et al., the pro α 2(I) chains found in the molecule of type I procollagen were of mouse origin. Hence, the type I procollagen synthesized is a hybrid molecule of human and mouse origin. Similarly, the system of Lee et al. expressed an exogenous pro α 2(I) gene to generate type I procollagen in which the pro α 1(I) chains were of rat origin. The present invention provides methods for the production of procollagens or collagens derived solely from transfected procollagen and collagen genes, but these methods are not limited to the production of procollagen and collagen derived solely from transfected genes.

An advantage of human collagens of the present invention is that these collagens will not produce allergic responses in man. Moreover, collagen of the present invention prepared from cultured cells should be of a higher quality than collagen obtained from animal sources, and should form larger and more tightly packed fibers. These higher quality proteins should form deposits in tissues that last much longer than the currently available commercial materials. It is known that using currently available methods, most injections of collagen for cosmetic purposes have to be repeated as frequently as every 6 months. Human protein of the present invention should last much longer after injection into human tissues.

Methods of the present invention provide a practical source of a human fibrillar collagen similar to animal collagens that are widely used for injection to remove cosmetic wrinkles, and cosmetic defects of other natures, and are also being used to restore the tensile strength of tissues such as the sphincter of the bladder in the treatment of urinary

- 11 -

incontinence. Animal collagens are also used in mixtures with ceramics and other materials to fill in defects in bone and enhance bone growth. Type I collagen from animal sources has been used commercially. However, a convenient source of human 5 collagen for therapeutic use is still sorely needed.

Further, the present invention contemplates that human type II procollagen, the precursor of the major collagen of cartilage may have special use in the repair of cartilage damage. Moreover, modified human type I procollagen comprising 10 a pro α 1(I) trimer expressed according to the methods in the present invention is also contemplated. Also, type I procollagen comprised of two pro α 1(I) and one pro α 2(I) chains derived from transfected human genes is contemplated. Also, type III procollagen comprised of three pro α 1(III) chains 15 derived from transfected human genes is contemplated. In addition, specifically engineered forms of these collagens are contemplated.

Methods are provided for synthesizing fibrillar collagen in cells comprising transfecting at least one human 20 procollagen or collagen gene into cells and selecting transfected cells that comprise molecules derived from a procollagen or collagen gene or genes, other than the [pro α 1(I)]₂pro α 2(I) molecule consisting of human pro α 1(I) moieties and non-human pro α 2(I) moieties, or non-human α 1(I) 25 moieties and human α 2(I) moieties. Further, methods whereby at least one of the human procollagen genes is a mutant, variant, hybrid or recombinant gene are also contemplated. Additionally, the present invention provides methods whereby substantially all cells transfected with at least one 30 procollagen gene comprise type III and other procollagen genes. Further, methods are contemplated wherein transfected cells are human tumor cells, especially but not limited to HT-1080 cells. Methods are also provided whereby transfected cells comprise independently substantially no endogenously derived collagen 35 molecules, endogenously derived type I procollagen molecules, endogenously derived type II procollagen molecules, endogenously derived type III procollagen molecules, or

- 12 -

endogenously derived type IV collagen molecules. Other methods are provided whereby substantially all of the transfected cells comprise at least one transfected human procollagen gene and express procollagen or collagen molecules having at least one 5 chain derived from the transfected gene, other than the $[\text{pro}\alpha 1(\text{I})]_2\text{pro}\alpha 2(\text{I})$ collagen consisting of human $\text{pro}\alpha 1(\text{I})$ moieties and non-human $\text{pro}\alpha 2(\text{I})$ moieties, or non-human $\text{pro}\alpha 1(\text{I})$ moieties and human $\text{pro}\alpha 2(\text{I})$ moieties. Other preferred methods are provided whereby substantially all transfected cells 10 comprise at least one transfected human procollagen gene and express procollagen molecules having three chains derived from the transfected collagen gene or genes.

The present invention is further illustrated by the following examples, which are not intended to be limiting in 15 any way.

EXAMPLES

Example 1 Synthesis of Human Type II Procollagen

A recombinant COL1A1 gene construct employed in the present invention comprised a fragment of the 5'-end of COL1A1 20 having a promotor, exon 1 and intron 1 fused to exons 3 through 54 of a COL2A1 gene. The hybrid construct was transfected into HT-1080 cells. These cells were co-transfected with a neomycin-resistance gene and grown in the presence of the neomycin analog G418. The hybrid construct was used to 25 generate transfected cells.

A series of clones were obtained that synthesized mRNA for human type II procollagen. To analyze the synthesized proteins, the cells were incubated with [^{14}C]proline and the ^{14}C -labeled medium proteins were analyzed by gel electrophoresis. 30 See Figure 1. As indicated in Lane 1, the medium proteins contained the expected type II procollagen comprised of $\text{pro}\alpha 1(\text{II})$ chains together with $\text{pro}\alpha 1(\text{IV})$ and $\text{pro}\alpha 2(\text{IV})$ chains of type IV collagen normally synthesized by the cells. As indicated in Lanes 2 and 3, the type II procollagen was readily 35 purified by a single step of ion exchange chromatography. The type II procollagen secreted into the medium was correctly

- 13 -

folded by a protease-thermal stability test. See Figure 2.

Example 2 Synthesis of Human Type I Procollagen

As a second example, HT-1080 cells were co-transfected with a COL1A1 gene and a COL1A2 gene. Both genes consisted of 5 a cytomegalic virus promoter linked to a full-length cDNA. The COL1A2 gene construct but not the COL1A1 gene construct contained a neomycin-resistance gene. The cells were selected for expression of the COL1A2-neomycin resistance gene construct by growth in the presence of the neomycin-analog G418. The 10 medium was then examined for expression of the COL1A1 with a specific polyclonal antibody for human pro α 1(I) chains. The results (see Figure 3) demonstrated that the cells synthesized human type I procollagen that was probably comprised of the normal heterotrimeric structure of two pro α 1(I) chains and one 15 pro α 2(I) chain.

Table 1 presents a summary of the DNA constructs containing human procollagen genes. The constructs were assembled from discrete fragments of the genes or cDNAs from the genes together with appropriate promoter fragments.

<u>Constructs</u>	<u>5'-end</u>	<u>Central Region</u>	<u>3'-end</u>	<u>Protein product</u>
5	Promoter (2.5 kb) + exon 1 + intron 1 from COL1A1	Exons 3 to 54 from COL2A1	3.5 kb SphI/SphI fragment from 3'-end of COL2A1	Human type II procollagen, [pro α 1(II)] ₃
10	Promoter (2.5 kb) of COL1A1	Exons 1 to 54 from COL2A1	3.5 kb SphI/SphI fragment from 3'-end of COL2A1	Human type II procollagen, [pro α 1(II)] ₃
15	Promoter (2.5 kb) + exon 1 + intron 1 + half of exon 2 from COL1A1	CDNA for COL1A1 except for first 1 1/2 exons	0.5 kb fragment from COL1A1	Human type I procollagen, [pro α 1(I)] ₃
20	Cytomegalic virus promoter	CDNA from COL1A1		Human type I procollagen, [pro α 1(I)] ₃
	Cytomegalic virus promoter	CDNA from COL1A2		Human type I [pro α 1(I)] ₂ pro α 2(I) when expressed with construct C or D

- 15 -

Example 3 Cell Transfections

For cell transfection experiments, a cosmid plasmid clone containing the gene construct was cleaved with a restriction endonuclease to release the construct from the 5 vector. A plasmid vector comprising a neomycin resistance gene, Law et al., *Molec. Cell Biol.* 1983, 3, 2110-2115, was linearized by cleavage with BamHI. The two samples were mixed in a ratio of approximately 10:1 gene construct to neomycin-resistant gene, and the mixture was then used for 10 transfection of HT-1080 cells by calcium phosphate coprecipitation, Sambrook et al., Molecular Cloning. A Laboratory Manual, Cold Spring Harbor Laboratory Press, Second Edition (1989). DNA in the calcium phosphate solution was layered onto cultured cells with about 10 μ g of chimeric gene 15 construct per 100 ml plate of preconfluent cells. Cells were incubated in DMEM containing 10% newborn calf serum for 10 hours. The samples were subjected to glycerol shock by adding a 15% glycerol solution for 3 minutes. The cells were then transferred to DMEM medium containing newborn calf serum for 20 24 hours and then to the same medium containing 450 μ g/ml of G418. Incubation in the medium containing G418 was continued for about 4 weeks with a change of medium every third day. G418-resistant cells were either pooled or separate clones obtained by isolating foci with a plastic cylinder and 25 subcultured.

Example 4 Western blotting

For assay of expression of the COL2A1 gene, polyclonal antibodies were prepared in rabbits using a 23-residue synthetic peptide that had an amino acid sequence 30 found in the COOH-terminal telopeptide of type II collagen. See Cheah et al., *Proc. Natl. Acad. Sci. USA* 1985, 82, 2555-2559. The antibody did not react by Western blot analysis with pro α chains of human type I procollagen or collagen, human type II procollagen or collagen, or murine type I 35 procollagen. For assay of expression of the COL1A1 genes, polyclonal antibodies that reacted with the COOH-terminal

- 16 -

polypeptide of the pro α 1(I) chain were employed. See Olsen et al., *J. Biol. Chem.* 1991, 266, 1117-1121.

Culture medium from pooled clones or individual clones was removed and separately precipitated by the addition 5 of solid ammonium sulfate to 30% saturation and precipitates were collected by centrifugation at 14,000 x g and then dialyzed against a buffer containing 0.15 M NaCl, 0.5 mM EDTA, 0.5 mM N-ethylmaleimide, 0.1 mM and p-aminobenzamidine, and 50 mM Tris-HCl (pH 7.4 at 4°C). Aliquots of the samples were 10 heated to 10°C for 5 minutes in 1% SDS, 50 mM DTT and 10% (v/v) glycerol, and separated by electrophoresis on 6% polyacrylamide gels using a mini-gel apparatus (Holford SE250, Holford Scientific) run at 125 V for 90 minutes. Separated proteins were electroblotted from the polyacrylamide gel at 15 40 V for 90 minutes onto a supported nitrocellulose membrane (Schleicher and Schuell). The transferred proteins were reacted for 30 minutes with the polyclonal antibodies at a 1:500 (v/v) dilution. Proteins reacting with the antibodies were detected with a secondary anti-rabbit IgG antibody 20 coupled to alkaline phosphatase (Promega Biotech) for 30 minutes. Alkaline phosphatase was visualized with NBT/BCIP (Promega Biotech) as directed by the manufacturer.

**Example 5 Demonstration of Correct Folding
of the Secreted Procollagens**

25 To demonstrate that the procollagens synthesized and secreted in the medium by the transfected cells were correctly folded, the medium proteins were digested with high concentrations of proteases under conditions in which only correctly folded procollagens and collagens resist digestion. 30 For digestion with a combination of trypsin and chymotrypsin, the cell layer from a 25 cm flask was scraped into 0.5 ml of modified Krebs II medium containing 10 mM EDTA and 0.1% Nonidet P-40 (Sigma). The cells were vigorously agitated in a Vortex mixer for 1 minute and immediately cooled to 4°C. 35 The supernatant was transferred to new tubes. The sample was preincubated at the temperature indicated for 10 minutes and the digestion was carried out at the same temperature for 2

- 17 -

minutes. For the digestion, a 0.1 volume of the modified Krebs II medium containing 1 mg/ml trypsin and 2.5 mg/ml α -chymotrypsin (Boehringer Mannheim) was added. The digestion was stopped by adding a 0.1 volume of 5 mg/ml soybean trypsin inhibitor (Sigma).

For analysis of the digestion products, the sample was rapidly immersed in boiling water for 2 minutes with the concomitant addition of a 0.2 volume of 5 x electrophoresis sample buffer that consisted of 10% SDS, 50% glycerol, and 10 0.012% bromphenol blue in 0.625 M Tris-HCl buffer (pH 6.8). Samples were applied to SDS gels with prior reduction by incubating for 3 minutes in boiling water after the addition of 2% 2-mercaptoethanol. Electrophoresis was performed using the discontinuous system of Laemmli, *Nature* 1979, 227, 680-15 685, with minor modifications described by de Wet et al., *Journal of Biological Chemistry* 1983, 258, 7721-7728.

**Example 6 Specifically Engineered
Procollagens and Collagens**

As indicated in Figure 4, a hybrid gene consisting 20 of some genomic DNA and some cDNA for the pro α 1(I) chain of human type I procollagen was the starting material. The DNA sequence of the hybrid gene was analyzed and the codons for amino acids that formed the junctions between the repeating D-periods were modified in ways that did not change the amino 25 acids encoded but did create unique sites for cleavage of the hybrid gene by restriction endonucleases.

A. Recombinant procollagen or collagen

The D3-period of pro α 1(I) is excised using SrfI and NaeI restriction nucleases. The bases coding for the amino 30 acids found in the collagenase recognition site present in the D3 period are modified so that they code for a different amino acid sequence. The cassette is amplified and reinserted in the gene. Expression of the gene in an appropriate host cell will result in type I collagen which can not be cleaved by 35 collagenase.

- 18 -

B. Procollagen or collagen deletion mutants

A D2 period cassette (of the pro α 1(I) chain) is excised from the gene described above by digestion with SmaI. The gene is reassembled to provide a gene having a specific 5 in-frame deletion of the codons for the D2 period.

C. Procollagen or collagen addition mutants

Multiple copies of one or more D-cassettes may be inserted at the engineered sites to provide multiple copies of desired regions of procollagen or collagen.

10 Example 7 Expression of Human Prolyl 4-Hydroxylase in a Recombinant DNA System

To obtain expression of the two genes for prolyl 4-hydroxylase in insect cells, the following procedures were carried out. The baculovirus transfer vector pVL α 58 was 15 constructed by digesting a pBluescript (Stratagene) vector containing in the SmaI site the full-length cDNA for the α subunit of human prolyl 4-hydroxylase, PA-58 (Helaakoski, T. et al., *Proc. Natl. Acad. Sci. USA* 1989, 86, 4392-4396), with PstI and BamHI, the cleavage sites which closely flank the 20 SmaI site. The resulting PstI-PstI and PstI-BamHI fragments containing 61 bp of the 5' untranslated sequence, the whole coding region, and 551 bp of the 3' untranslated sequence were cloned to the PstI-BamHI site for the baculovirus transfer vector pVL1392 (Luckow, V.A. and Summers, M.D., *Virology* 1989, 25 170, 31-39). The baculovirus transfer vector pVL α 59 was similarly constructed from pVL1392 and another cDNA clone, PA-59 (Helaakoski, T. et al., *supra*), encoding the α subunit of human prolyl 4-hydroxylase. The cDNA clones PA-58 and PA-59 differ by a stretch of 64 bp.

30 The pVL β vector was constructed by ligation of an EcoRI-BamHI fragment of a full-length cDNA for the β subunit of human prolyl 4-hydroxylase, S-138 (Pihlajaniemi, T. et al., *EMBO J.* 1987, 6, 643-649) containing 44 bp of the 5' untranslated sequence, the whole coding region, and 207 bp of 35 the 3' untranslated sequence to EcoRI/BamHI-digested pVL1392. Recombinant baculovirus transfer vectors were cotransfected

- 19 -

into Sf9 cells (Summers, M.D. and Smith, G.E., *Tex. Agric. Exp. St. Bull.* 1987, 1555, 1-56) with wild-type *Autographa californica* nuclear polyhedrosis virus (AcNPV) DNA by calcium phosphate transfection. The resultant viral pool in the supernatant of the transfected cells was collected 4 days later and used for plaque assay. Recombinant occlusion-negative plaques were subjected to three rounds of plaque purification to generate recombinant viruses totally free of contaminating wild-type virus. The screening procedure and isolation of the recombinant viruses essentially followed by the method of Summers and Smith, *supra*. The resulting recombinant viruses from pVL α 58, pVL α 59, and pVL β were designated as the α 58 virus, α 59 virus and β virus, respectively.

15 Sf9 cells were cultured in TNM-FH medium (Sigma) supplemented with 10% fetal bovine serum at 27°C either as monolayers or in suspension in spinner flasks (Techne). To produce recombinant proteins, Sf9 cells seeded at a density of 10^6 cells per ml were infected at a multiplicity of 5-10 20 with recombinant viruses when the α 58, α 59, or β virus was used alone. The α and β viruses were used for infection in ratios of 1:10-10:1 when producing the prolyl 4-hydroxylase tetramer. The cells were harvested 72 hours after infection, homogenized in 0.01 M Tris, pH 7.8/0.1 M NaCl/0.1 M glycine/10 25 μ M dithiothreitol/0.1% Triton X-100, and centrifuged. The resulting supernatants were analyzed by SDS/10% PAGE or nondenaturing 7.5% PAGE and assayed for enzyme activities. The cell pellets were further solubilized in 1% SDS and analyzed by SDS/10% PAGE. The cell medium at 24-96 hours 30 postinfection was also analyzed by SDS/10% PAGE to identify any secretion of the resultant proteins into the medium. The cells in these experiments were grown in TNM-FH medium without serum.

When the time course of protein expression was 35 examined, Sf9 cells infected with recombinant viruses were labeled with [35 S]methionine (10 μ Ci/ μ l; Amersham; 1 Ci=37 CBq) for 2 hours at various time points between 24 and 50

- 20 -

hours after infection and collected for analysis by SDS/10% PAGE. To determine the maximal accumulation of recombinant protein, cells were harvested at various times from 24 to 96 hours after infection and analyzed on by SDS/10% PAGE. Both 5 the 0.1% Triton X-100- and 1% SDS-soluble fractions of the cells were analyzed. Prolyl 4-hydroxylase activity was assayed by a method based on the decarboxylation of 2-oxo[1-¹⁴C]glutarate (Kivirikko, K.I., and Myllyla, R., *Methods Enzymol.* 1982, 82, 245-304). The Km values were determined 10 by varying the concentrations of one substrate in the presence of fixed concentration of the second, while the concentrations of the other substrates were held constant (Myllyla, R., Tuderman, L., and Kivirikko, K.I., *Eur. J. Biochem.* 1977, 80, 349-357). Protein disulfide-isomerase activity of the β 15 subunit was measured by glutathione:insulin transhydrogenase assay (Carmichael et al., *J. Biol. Chem.* 1977, 252, 7163-7167). Western blot analysis was performed using a monoclonal antibody, 5B5, to the β subunit of human prolyl 4-hydroxylase (Hoyhtya, M. et al., *Eur. J. Biochem.* 1984, 141, 477-482). 20 Prolyl 4-hydroxylase was purified by a procedure consisting of poly(L-proline) affinity chromatography, DEAE-cellulose chromatography, and gel filtration (Kivirikko, K.I., and Myllyla, R., *Methods Enzymol.* 1987, 144, 96-114).

Figure 5 presents analysis of the prolyl 4- 25 hydroxylase synthesized by the insect cells after purification of the protein by affinity-column chromatography. When examined by polyacrylamide gel electrophoresis in a non-denaturing gel, the recombinant enzyme co-migrated with the tetrameric and active form of the normal enzyme purified from 30 chick embryos. After the purified recombinant enzyme was reduced, the α - and β - subunits were detected. Table 2 presented data on the enzymic activity of the recombinant enzyme. The Km values were determined by varying the concentration of one substrate in the presence of fixed 35 concentrations of the second while the concentration of the other substrates were held constant.

- 21 -

TABLE 2

Substrate	Km value, μ M		
	$\alpha 58, \beta$	$\alpha 59, \beta$	Chick enzyme
Fe ⁺²	4	4	4
2-oxoglutarate	22	25	22
5 ascorbate	330	330	300
(Pro-Pro-Gly) ₁₀	18	18	15-20

As indicated, the Michales-Menton (Km) values for the recombinant enzyme were the same as for the authentic normal enzyme from chick embryos.

10 Since the transfected insect cells synthesize large amounts of active prolyl 4-hydroxylase, they are appropriate cells to transfect with genes of the present invention coding for procollagens and collagens so as to obtain synthesis of large amounts of the procollagens and collagens. Transfection 15 of the cells with genes of the present invention is performed as described in Example 3.

Example 8 Expression of Recombinant Collagen Genes in *Saccharomyces cerevisiae* Yeast Expressing Recombinant Genes for Prolyl 4-Hydroxylase

20 The yeast *Saccharomyces cerevisiae* can be used with any of a large number of expression vectors. One of the most commonly employed expression vectors is the multi-copy 2 μ plasmid that contains sequences for propagation both in yeast and *E. coli*, a yeast promoter and terminator for efficient 25 transmission of the foreign gene. Typical examples of such vectors based on 2 μ plasmids are pWYG4 that has the 2 μ ORI-STB elements, the GAL1 promoter, and the 2 μ D gene terminator. In this vector an Ncol cloning site containing the ATG that is used to insert the gene for either the α or β subunit of 30 prolyl 4-hydroxylase. As another example, the expression vector can be pWYG7L that has intact 2 μ ORI, STB, REP1 and REP2, the GAL7 promoter, and uses the FLP terminator. In this vector, the gene for either the α or β subunit of prolyl 4-

- 22 -

hydroxylase is inserted in the polylinker with its 5' ends at a BamHI or Ncol site. The vector containing the prolyl 4-hydroxylase gene is transformed into *S. cerevisiae* either after removal of the cell wall to produce spheroplasts that 5 take up DNA on treatment with calcium and polyethylene glycol or by treatment of intact cells with lithium ions. Alternatively, DNA can be introduced by electroporation. Transformants can be selected by using host yeast cells that are auxotrophic for leucine, tryptophane, uracil or histidine 10 together with selectable marker genes such as LEU2, TRP1, URA3, HIS3 or LEU2-D. Expression of the prolyl 4-hydroxylase genes driven by the galactose promoters can be induced by growing the culture on a non-repressing, non-inducing sugar so that very rapid induction follows addition of galactose; 15 by growing the culture in glucose medium and then removing the glucose by centrifugation and washing the cells before resuspension in galactose medium; and by growing the cells in medium containing both glucose and galactose so that the glucose is preferentially metabolized before galactose- 20 induction can occur. Further manipulations of the transformed cells are performed as described above to incorporate genes for both subunits of prolyl 4-hydroxylase and desired collagen or procollagen genes into the cells to achieve expression of collagen and procollagen that is adequately hydroxylated by 25 prolyl 4-hydroxylase to fold into a stable triple helical conformation and therefore accompanied by the requisite folding associated with normal biological function.

Example 9 Expression of Recombinant Collagen Genes in
30 *Pichia pastoris* Yeast Expressing Recombinant
 Genes for Prolyl 4-Hydroxylase

Expression of the genes for prolyl 4-hydroxylase and procollagens or collagens can also be in non-*Saccharomyces* yeast such as *Pichia pastoris* that appear to have special advantages in producing high yields of recombinant protein in 35 scaled-up procedures. Typical expression in the methylotroph *P. pastoris* is obtained by the promoter from the tightly regulated AOX1 gene that encodes for alcohol oxidase and can

- 23 -

be induced to give high levels of recombinant protein driven by the promoter after addition of methanol to the cultures. Since *P. pastoris* has no native plasmids, the yeast is employed with expression vectors designed for chromosomal 5 integration and genes such as HIS4 are used for selection. By subsequent manipulations of the same cells expression of genes for procollagens and collagens described herein is achieved under conditions where the recombinant protein is adequately hydroxylated by prolyl 4-hydroxylase and, 10 therefore, can fold into a stable helix that is required for the normal biological function of the proteins in forming fibrils.

CLAIMS

What is claimed:

1. Cells, substantially all of which comprise at least one transfected human procollagen or collagen gene, and 5 express procollagen or collagen molecules having at least one chain derived from said procollagen or collagen gene or genes, other than the $[\text{pro}\alpha 1(\text{I})]_2\text{pro}\alpha 2(\text{I})$ collagen molecule consisting of human $\text{pro}\alpha 1(\text{I})$ moieties and non-human $\text{pro}\alpha 2(\text{I})$ moieties, or non-human $\text{pro}\alpha 1(\text{I})$ moieties and human $\text{pro}\alpha 2(\text{I})$ moieties.
- 10 2. The cells of claim 1 having procollagen or collagen molecules in which the three chains of said procollagen or collagen molecules are derived from said transfected gene.
- 15 3. The cells of claim 1 wherein one of said human procollagen genes is the COL1A1 gene encoding the $\text{pro}\alpha 1(\text{I})$ chain of human type I procollagen.
4. The cells of claim 3 wherein a second of said human procollagen genes is the COL1A2 gene encoding the $\text{pro}\alpha 2(\text{I})$ chain of human type I procollagen.
- 20 5. The cells of claim 1 wherein one of said human procollagen genes is the COL2A1 gene encoding the $\text{pro}\alpha 1(\text{II})$ chain of human type II procollagen.
- 25 6. The cells of claim 1 wherein one of said human procollagen genes is the COL3A1 genes encoding the $\text{pro}\alpha 1(\text{III})$ chain of the human type III procollagen.
7. The cells of claim 1 wherein at least one of said genes is a mutant, variant, hybrid or recombinant gene.
8. The cells of claim 1 being mammalian cells.
9. The cells of claim 8 being human tumor cells.

- 29 -

10. The cells of claim 8 wherein said cells are transfected with a post-translational enzyme.

11. The cells of claim 10 wherein the post-translational enzyme is prolyl 4-hydroxylase.

5 12. The cells of claim 1 being insect cells.

13. The cells of claim 12 wherein said cells are transfected with a post-translational enzyme.

14. The cells of claim 13 wherein said post-translational enzyme is prolyl 4-hydroxylase.

10 15. The cells of claim 1 being yeast cells.

16. The cells of claim 15 wherein said cells are transfected with a post-translational enzyme.

17. The cells of claim 16 wherein said post-translational enzyme is prolyl 4-hydroxylase.

15 18. A method for synthesizing procollagen or collagen in cells comprising:

transfecting at least one procollagen or collagen gene into cells;

20 culturing said cells under conditions such that said transfected procollagen or collagen genes are expressed;

selecting transfected cells that comprise at least one molecule derived from said procollagen or collagen gene or genes, other than the [pro α 1(I)]₂pro α 2(I) collagen molecule consisting of human pro α 1(I) moieties and non-human pro α 2(I) 25 moieties, or non-human pro α 1(I) moieties and human pro α 2(I) moieties.

19. The method of claim 18 wherein one of said human procollagen genes is the COL1A1 gene encoding the pro α 1 (I)

- 30 -

chain of human type I procollagen.

20. The method of claim 19 wherein a second of said procollagen genes is the COL1A2 gene encoding the pro α 2(I) chain of human type I procollagen.

5 21. The method of claim 18 wherein one of said human procollagen genes is the COL2A1 gene encoding the pro α 1(II) chain of human type II procollagen.

10 22. The method of claim 18 wherein one of said human procollagen genes is the COL3A1 gene encoding the pro α 1 (III) chain of human type III procollagen.

23. The method of claim 18 wherein at least one of said genes is a mutant, variant, hybrid or recombinant gene.

24. The method of claim 18 wherein said cells are mammalian cells.

15 25. The method of claim 24 wherein said cells are human tumor cells.

26. The method of claim 24 wherein said cells are transfected with a post-translational enzyme.

20 27. The method of claim 26 wherein said post-translational enzyme is prolyl 4-hydroxylase.

28. The method of claim 18 wherein said cells are insect cells.

29. The method of claim 28 wherein said cells are transfected with a post-translational enzyme.

25 30. The cells of claim 29 wherein said post-translational enzyme is prolyl 4-hydroxylase.

- 31 -

31. The method of claim 18 wherein said cells are yeast cells.

32. The method of claim 31 wherein said cells are transfected with a post-translational enzyme.

5 33. The method of claim 32 wherein said post-translational enzyme is prolyl 4-hydroxylase.

34. A collagen produced by the cells of claim 1.

35. A collagen produced by the method of claim 18.

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	Journal of Biological Chemistry, volume 266, number 22, issued 05 August 1991, L. Ala-Kokko et al, "Expression of a human cartilage procollagen gene (COL2A1) in mouse 3T3 cells", pages 14175-14178, see entire document.	1-35
X	Matrix, volume 10, number 4, issued 1990, L. Ala-Kokko et al, "Expression of the human type II procollagen gene in mouse 3T3 cells by use of a vector containing the promoter region, the first exon and the first intron of the pro-alpha1(I) chain for human type I procollagen", page 234, see entire document.	1-35
Y	Journal of Biological Chemistry, volume 266, number 2, issued 15 January 1991, A.S. Olsen et al, "High levels of expression of a minogene version of the human pro-alpha1(I) collagen gene in stably transfected mouse fibroblasts", pages 1117-1121, see entire document.	1-35

Further documents are listed in the continuation of Box C. See patent family annex.

Special categories of cited documents:	
"A"	document defining the general state of the art which is not considered to be part of particular relevance
"E"	earlier document published on or after the international filing date
"L"	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
"O"	document referring to an oral disclosure, use, exhibition or other means
"P"	document published prior to the international filing date but later than the priority date claimed
"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"&"	document member of the same patent family
